

Lunar Meteor Schedule and Observing Plan for 2022

As has been the case for the last several years, I have outlined the plan to monitor the moon on a regular basis both inside and outside normal annual showers. Each month, for a total of up to 14 days per month, we are coordinating observations of the Earthshine portion of the moon for background (including the minor showers when they fall during this time) meteor impact flux. A typical run of observations starts three days after New Moon and continues until two days past First Quarter. The run resumes two days before Last Quarter and continues until three days prior to New Moon. The actual interval will depend on the lunar elevation and elongation as well as the ability of the observer to control stray light in one's system. The year's two total lunar eclipses will be included in this observation program as well.

Table. Working list of meteor showers, courtesy of the International Meteor Organization.

Observations of the moon during annual showers will occur during routine monthly observations, but observers who are limited in terms of time spent observing are encouraged to plan for annual showers first and to observe for a day or two either side of (and including) shower maximum.

The table on the previous page, from the Working list of meteor showers published annually at www.imo.net (the International Meteor Organization) shows information about the annual showers. Entries in **bold** delineate a shower that is favored for lunar activity, that is, when maximum occurs during the specified interval. The shower name and IMO designation is given in the first column. The interval of activity is presented in the second column with the date of maximum (Earth-based) in the third column. The velocity of the meteoroids at infinity is presented in the next column, which is followed by the population index. The population index, r , is a measure of the distribution of meteoroid sizes at maximum. A larger value of r indicates a larger proportion of smaller particles and is less favorable for lunar meteor studies. Smaller r -values indicate more large particles, translating into a greater probability of observing lunar impacts. Finally, the Zenithal Hourly Rate, as observed on Earth, is given.

We encourage observers to watch the moon a day or two before and after the predicted peak date of an annual shower. The difference in ZHR peak time from Earth to the moon is up to ± 7 hours...later for evening phase, earlier for morning phase. Some showers, such as the Orionids, have a broader peak, while others like the Quadrantids have a narrow peak. The dates of monthly observations are given in the next table. The cut-off dates for one's observing program will vary with year and latitude of observer, which affects the ecliptic angle and the lunar visibility.

In addition, we plan observations for the two total lunar eclipses this year: **May 16** and **November 8**. Each features 125 minutes of totality, with an additional 30 minutes either side of totality that can be used to monitor the dark portion of the eclipsed Moon, Any questions concerning this plan can be directed to the ALPO Lunar Meteoritic Impact Search Coordinator, Mr. Brian Cudnik, at bmcudnik@gmail.com.
